

Healthy Weather - Static Export + PHP Backend Deployment Guide

Overview

This project has been successfully converted to use:

- **Frontend:** Static HTML/CSS/JS (no server runtime required)
- **Backend:** PHP REST API with SQLite database
- **Logo:** Updated to use the new HW_icon_teal.png

Ready-to-Deploy Files

The `/deployment` directory contains everything you need:

```
deployment/
├── index.html          # Static website (main page)
├── logo.png            # Company logo
├── api/                # PHP backend
│   ├── config.php      # Database config & helpers
│   ├── allergy-signup.php
│   ├── contact.php
│   ├── .htaccess       # Apache configuration
│   └── README.md       # API documentation
└── data/
    └── dev.db          # SQLite database
```

DreamHost Deployment Steps

1. Upload Files to DreamHost

Upload to `public_html/` :

- `index.html` (main website file)
- `logo.png` (company logo)
- `api/` directory (entire folder)

Upload to private directory (e.g., `/home/username/data/`):

- `dev.db` (SQLite database file)

2. Configure Database Path

Edit `public_html/api/config.php` and update the database path:

```
define('DB_PATH', '/home/username/data/dev.db');
```

Replace `/home/username/` with your actual DreamHost home directory path.

3. Set File Permissions

```
chmod 755 api/*.php
chmod 644 /home/username/data/dev.db
chown www-data:www-data /home/username/data/dev.db # If needed
```

API Endpoints

- **POST** /api/allergy-signup.php - Email signup for Allergy Tracker
- **POST** /api/contact.php - Contact form submissions

Both endpoints:

- Save data to SQLite database
- Send email notifications
- Return JSON responses
- Include CORS headers for cross-origin requests

Email Configuration

The PHP files are configured to send emails to:

- **Allergy signups:** allergy@healthyweather.us
- **Contact forms:** info@healthyweather.us

Database Schema

SQLite database contains:

- **allergy_signups:** (id, email, createdAt, status)
- **contact_submissions:** (id, name, email, message, createdAt, status)

Security Features

- Database stored in non-public directory
- Input sanitization and validation
- SQL injection protection via prepared statements
- XSS protection via htmlspecialchars
- CORS headers properly configured
- Error logging (not displayed to users)

Testing Locally

To test the PHP backend locally (if you have PHP installed):

```
cd deployment
php -S localhost:8080
```

Then visit `http://localhost:8080` to test the static site with PHP backend.

Notes

- The static website (`index.html`) is a complete single-page application
- No Next.js server runtime required for deployment
- Forms will work seamlessly with the PHP backend
- Logo has been updated to the new teal icon
- Responsive design works on all devices
- All original functionality preserved
